Maple Syrup: Climate change impacts on production and adaptation strategies

Adaptation Issue: Maple syrup is a major cultural resource in the Northeast and Midwest U.S. with a strong link to climate. The sugar maple tree’s distribution is affected by high temperatures, low rainfall, and unseasonable variation in the onset of spring warming events. NE CASC and ACERnet researchers are working with maple sap harvesters, foresters, and landscape-scale conservation organizations to determine what to expect and how to adapt.

Why it matters

The cultural and economic importance of sugar maple trees is nearly unrivaled among eastern North America tree species. Sugar maple lumber commands a premium price, its foliage supports a seasonal tourist industry, and it is widely planted both within and beyond its natural range as a shade tree. Tapping maple trees for sap, one of the few wild-harvested agricultural products remaining in North America, has long been a part of the cultural fabric of the Northeastern and Midwestern US.

ACERnet, an on-line resource and research network, was formed to centralize information on the impacts of climate on sugar maple (genus Acer) and suggested adaptation strategies. The ACERnet research team is monitoring sap flow at sites across sugar maples’ range, from Virginia to Quebec, to understand how climate effects sap flow, sugar content, and chemical composition, which together influence the quality and quantity of maple syrup produced. Read more at: http://blogs.umass.edu/acernet/

Mike Puffenbarger is the owner of Southernmost Maple, a family-operated Virginia business. He supplies data on sugar content, sap volume and sap samples to ACERnet. Compared with all the other study sites, their syrup has the highest antioxidant/phenolic content and, according to customers, is the best tasting, too!

This work is supported by the Northeast Climate Adaptation Science Center, which is managed by the National Climate Adaptation Science Center.
Some of the ways climate will impact sugar maple:

- **Availability of trees to tap**
  Suitable habitat for the sugar maple tree has been predicted to decline in much of its U.S. range by 2100.

- **Tree health**
  Reduced snow pack during the winter can cause root die-back and reduced shoot growth, and more frequent spring frost can negatively impact trees that respond to warmer temperatures by breaking bud earlier. Growth declines in mature trees in recent decades may be related to rising temperatures.

- **Tapping season characteristics**
  Maple syrup producers are already reporting that the tapping season is shorter, starting earlier, and becoming more variable.

- **Climate change effects on sap quality**
  Sap quality is determined by its sugar content, mineral profile, and secondary metabolite chemicals that create the distinct taste of maple syrup and impart its health attributes. Climate change is hypothesized to influence these aspects of sap quality.

How resources managers can apply these results:
Maple producers are implementing a variety of management strategies that may help buffer the industry from the negative effects of climate change.

- Diversifying species tapped including red maple and birch.
- Adopting technological advancements including improved vacuum tubing, spouts, and processing technology.
- Finding new markets for increased demand.
- Product innovation and marketing different attributes of maple.
- Expanding maple production to untapped forest areas and cultivating plantations.
- Alleviating other environmental stressors including effects of acid rain and pests to decrease the effects of climate change.
- Environmental modification including diversifying maple stands.
